I. Introduction

At present, many people are burdened by workloads, whether in work-related jobs or in the academic studies of every college student, in order to submit assignments on time and earn a passing grade. While it is better to manage time by dividing workloads, doing so often results in excessive duties, including the work itself. Throughout their academic studies, students have been struggling to cope with the workloads assigned to them and to finish them on time. In this sense, this results in overwork and burnout in their working conditions, creating a habit that affects the livelihoods of students and the global population alike, leading to excessive changes in their work habits, such as procrastination, sleep deprivation, and cognitive overload. This particular problem of the overworked burnout to the population relates to the modern problem that is facing today by students alike, such as college students and other related working sectors is important to tackle, enable to solve this problem by giving out ideal solutions to gain new knowledge so as to cope burnouts in working task, such as in academics and in the future job related course in their workloads. In this proposal, the author seeks to detail and scope the problem of burnout and its effects on others, and to outline an ideal theory of systematic practices for coping with burnout for students and the working population, creating an automated system to address overload burnout.

Problem description

In modern times, burnout can occur across various contexts, not just academic performance, but also non-academic workloads, leaving students overwhelmed by excessive tasks. Other sectors, such as the working population, have also faced excessive workloads, including spreadsheets in accountancy or IT jobs, debugging errors in their coding infrastructure, and creating projects that are still pending on their desktops. With this, the lasting impact of burnout on

students and employees impairs performance, leading to cognitive changes, procrastination, and, worse yet, increased stress that deteriorates one's health, not only physically but also mentally (Begum, 2024). According to the World Health Organization (2024), 50% of the population has experienced burnout throughout their daily lives, resulting in deterioration of their mental health. Working with high workloads helps boost social functioning and job performance; however, excessive workloads result in overwhelming stress not only for workers but also for students performing academic assignments, increasing the risk to their mental health. Students who work on nightly assignments have also been affected by heavy workloads, leading to sleep deprivation, procrastination, and academic underperformance. With this in mind, burnout results in overfatigue, procrastination, and changes in their diets, as students often don't eat before doing assignments, which deteriorates their mental and physical health. In addition, students felt tired from their workloads, making it impossible for them to complete their academic work and leaving it unfinished.

With this observation in mind, it is worth noting how burnout can affect the lives of students and working employees alike on a small scale. However, the data in the problem do not show how a large-cap-sized population manages burnout, or how to scale the sample to include students and working populations alike who have experienced burnout. Some of the problems are limited to the burnout scale, but it focuses only on the lasting impact of burnout, not on other work-environment side effects that are similarly related to burnout. Some challenges identified in the data are particularly relevant to students who have experienced academic performance issues, as this often does not reflect how, or whether, it affects their burnout and overwhelming feelings.

With this in mind, the proposal of ideal solutions can be mitigated by using a scheduling worksheet and the Pomodoro technique to manage time properly.

Proposal solution.

The proposed solution to mitigate overload burnout among students and working individuals is the development of an automated workload-tracking system integrated with an enhanced Pomodoro timer. This system is designed to help users systematically monitor, organize, and regulate their academic or work-related tasks through structured scheduling and performance tracking. By using digital tracking sheets, users can record tasks, deadlines, progress levels, and workload intensity, enabling them to visualize responsibilities clearly and prevent task accumulation. One of the key features of the system is the enhanced Pomodoro timer, which divides work into focused time intervals followed by automated, scheduled breaks to reduce cognitive overload and mental fatigue. Additional features include progress analytics, workload alerts, daily and weekly task summaries, and customizable focus sessions tailored to user energy levels.

The system primarily targets college students, working students, and professionals in high-demand sectors such as information technology, education, and administrative work, where prolonged screen time and task overload are common. By automating time management and rest enforcement, the system encourages consistent productivity, minimizes procrastination, and prevents prolonged work sessions that contribute to burnout. The expected impact of this solution includes improved time management, reduced stress levels, better academic and job performance, healthier work habits, and enhanced mental well-being. Overall, integrating workload tracking and time-based automation offers a sustainable, scalable approach to managing burnout among students and working individuals across sectors.

Conclusion

Burnout caused by excessive academic and work-related workloads has become a prevalent issue affecting students and working populations alike, leading to negative consequences such as stress, cognitive fatigue, sleep deprivation, and declining performance. Addressing this problem requires not only awareness but also structured and practical solutions. This proposal highlights the importance of implementing an automated workload-tracking and enhanced Pomodoro timer system as a sustainable approach to managing overload and burnout. By organizing tasks, regulating work intervals, and encouraging restorative breaks, the proposed system supports healthier productivity patterns and mental well-being. Ultimately, adopting systematic, automated time-management practices can help individuals effectively cope with burnout, improve performance, and foster long-term balance in both academic and professional environments.
